I tumori pancreatici

Pancreatic Solid and Cystic Neoplasms
Diagnostic Evaluation and Intervention

Mahmoud M. Al-Hawary, MD[a,*], Isaac R. Francis, MD[b], Michelle A. Anderson, MD, MSc[c]

KEYWORDS

• Pancreas • Neoplasms • Solid • Cystic • Imaging • Intervention

KEY POINTS

- Typical imaging techniques for the evaluation of pancreatic neoplasms include computed tomography, MR imaging, and, in selected cases, endoscopic ultrasound.
- High-quality dedicated imaging is essential for the diagnosis and assessment of pancreatic tumor extent, both of which are required to determine the best therapy for patients.
- Endoscopic ultrasound facilitates tissue or cyst fluid sampling in solid and cystic pancreatic neoplasms to help establish the diagnosis or narrow the differential diagnosis.
- The mainstay of treatment of pancreatic neoplasms is complete surgical resection when possible.
- Several noninvasive and invasive methods for treating solid and cystic pancreatic neoplasms are being investigated when surgery is not possible or is contraindicated.

I tumori pancreatici cistici

JOP. J Pancreas (Online) 2016 Sep 08; 17(5):452-465.

RESULTS

The first task is to classify the cysts into neoplastic and non-neoplastic cysts **(Table 1)** and the second task is to study the imaging morphology of the pancreatic cysts **(Table 2; Figure 1)**. MDCT has an accuracy of 56–85% for characterization of cystic pancreatic lesions [2, 3, 4]. MRI together with MRCP is superior in characterizing the cystic lesions as it has excellent soft tissue contrast resolution and spatial resolution. Previous studies indicate that MDCT and MRI are comparable in identifying malignant behaviour of cystic pancreatic lesions [5]. 3D MRCP sequences can better identify the communication of cystic lesions with the main pancreatic duct and also the internal content of these lesions [6]. Secretin-enhanced MRCP is further advancement and refinement in MRCP technique for better study of ductal anatomy and identifying communication of pancreatic cystic lesions with the pancreatic duct [7].

Imaging in pancreatic disease

Julien Dimastromatteo[1], Teresa Brentnall[2] and Kimberly A. Kelly[1]

Abstract | Pancreatic diseases, chronic pancreatitis, pancreatic cancer and diabetes mellitus, taken together, occur in >10% of the world population. Pancreatic diseases, as with other diseases, benefit from early intervention and appropriate diagnosis. Although imaging technologies have given clinicians an unprecedented toolbox to aid in clinical decision-making, advances in these technologies and development of molecular-based diagnostic tools could enable physicians to identify diseases at an even earlier stage and, thereby, improve patient outcomes. In this Review, we discuss and identify gaps in the use of imaging techniques for the early detection and appropriate treatment stratification of various pancreatic diseases, including diabetes mellitus, acute and chronic pancreatitis and pancreatic cancer. Imaging techniques discussed are MRI, CT, PET and ultrasonography. Additionally, the identification of new molecular targets for imaging and the development of contrast agents that are able to give molecular information in noninvasive radionuclear imaging and ultrasonography are emerging areas of innovation that could lead to increased diagnostic accuracy and improved patient outcomes.

Come si fa la diagnosi

Box 2 | **Imaging techniques glossary**

CT
Imaging procedure that uses special X-ray radiography equipment to create detailed pictures, or scans, of areas inside the body, also called computerized tomography and computerized axial tomography.

Confocal laser endomicroscopy (CLE)
Technique for obtaining real-time histology-like images from inside the human body.

Contrast-enhanced ultrasonography (CEUS)
Refers to use of intravenous contrast agents to improve visualization of the microvasculature and macrovasculature during an ultrasonographic assessment of organs.

Elastography
Imaging modality that maps the elastic properties of soft tissue.

Endoscopic retrograde cholangiopancreatography (ERCP)
Imaging procedure to visualize the pancreas or its ducts by X-ray radiography following injection of a contrast medium into the ducts at surgery via an endoscope.

Endoscopic ultrasonography (EUS)
Imaging procedure in which endoscopy is coupled with ultrasonography to visualize the internal organs.

Endoscopy
Nonsurgical procedure used to examine the digestive tract.

Endoscopy
Nonsurgical procedure used to examine the digestive tract.

Fluoroscopy
Real-time X-ray radiographic imaging that is especially useful for guiding diagnostic and interventional procedures.

Laparoscopy
Surgical intervention that uses a thin, lighted tube put through an incision in the belly to look at the abdominal organs.

Magnetic resonance cholangiopancreatography (MRCP)
A noninvasive imaging technique that uses MRI to obtain images of the biliary and pancreatic ducts.

MRI
Noninvasive imaging modality that uses a powerful magnetic field, radio frequency pulses and a computer to produce detailed pictures of organs, soft tissues, bone and virtually all other internal body structures.

PET
Imaging technique that uses a radioactive substance (beta$^+$ photon, also called a positron) to look for disease in the body.

Single-photon emission computed tomography (SPECT)
Imaging technique that uses a radioactive substance (gamma photon) to look for disease in the body.

Ultrasonography
Imaging modality that uses high-frequency acoustic wave to image the body. Involves the use of a small transducer (probe) and ultrasound-conductive gel placed directly on the skin.

Presurgical Evaluation of Pancreatic Cancer: A Comprehensive Imaging Comparison of CT Versus MRI

Fang-Ming Chen[1]
Jian-Ming Ni
Zhui-Yang Zhang
Lei Zhang
Bin Li
Chun-Juan Jiang

OBJECTIVE. The purpose of this study was to compare comprehensive CT and MRI in the presurgical evaluation of pancreatic cancer.

MATERIALS AND METHODS. Thirty-eight patients with pathologically proven pancreatic cancer were included in a retrospective study. CT with negative-contrast CT cholangiopancreatography and CT angiography (CTA) (CT image set) versus MRI with MRCP and MR angiography (MRI image set) were analyzed independently by two reviewers for tumor detection, extension, metastasis, vascular invasion, and resectability. These results were compared with the surgical and pathologic findings.

RESULTS. The rate of detection of tumors was higher with MRI than with CT but not significantly so (reviewer 1, $p = 1.000$; reviewer 2, $p = 0.500$). In the evaluation of vessel involvement, nodal status, and resectability, although CT had higher ROC AUC values than did MRI (reviewer 1, 0.913 vs 0.858, 0.613 vs 0.503, and 0.866 vs 0.774; reviewer 2, 0.879 vs 0.849, 0.640 vs 0.583, and 0.830 vs 0.815), the differences were not statistically significant ($p = 0.189$ vs 0.494, 0.328 vs 0.244, and 0.193 vs 0.813 for reviewers 1 and 2). In the evaluation of tumor extension and organ metastases in the 38 patients, correct diagnosis of one of two liver metastases was achieved with both image sets, one case of omental and one case of peritoneal seeding were underestimated, and one case of stomach invasion was overestimated.

CONCLUSION. MRI and CT had similar performance in the presurgical evaluation of pancreatic cancer.

Criteri di resecabilità

Table 3. Definition of resectability according to NCCN guidelines [19]

Resectability status	Arterial	Venous
Resectable	No arterial tumour contact [coeliac axis (CA), superior mesenteric artery (SMA), or common hepatic artery (CHA)]	No tumour contact with the superior mesenteric vein (SMV), or portal vein (PV) or <180° contact without vein contour irregularity
Borderline resectable	Pancreatic head/uncinate process • Solid tumour with CHA without extension to coeliac axis or hepatic artery bifurcation allowing for safe and complete resection and reconstruction • Solid tumour contact with the SMA ≤180° • Presence of variant arterial anatomy (e.g. accessory right hepatic artery) and the presence and degree of tumour contact should be noted if present as it may affect surgical planning Pancreatic body/tail • Solid tumour contact with the CA of ≤180° • Solid tumour contact with the CA of >180° without involvement of the aorta and with intact and uninvolved gastroduodenal artery (some members prefer these criteria to be in the unresectable category)	• Solid tumour contact with the SMV or PV of >180°, contact of ≤180° with contour irregularity of the vein or thrombosis of the vein but with suitable vessels proximal and distal to the site of involvement allowing for safe and complete resection and vein reconstruction • Solid tumour contact with the inferior vena cava (IVC)
Unresectable	• Distant metastases Pancreatic head/uncinate process • Solid tumour contact with SMA >180° • Solid tumour contact with the CA >180° • Solid tumour contact with the first jejunal SMA branch Body and tail • Solid tumour contact with the SMA and CA • Solid tumour contact with the CA and aorta	Pancreatic head/uncinate process • Unreconstructible SMV/PV due to tumour involvement or occlusion (can be due to tumour or bland thrombus) • Contact with most proximal draining jejunal branch into SMV Body and tail • Unreconstructible SMV/PV due to tumour involvement or occlusion (can be due to tumour or bland thrombus)

Diagnosi e Management

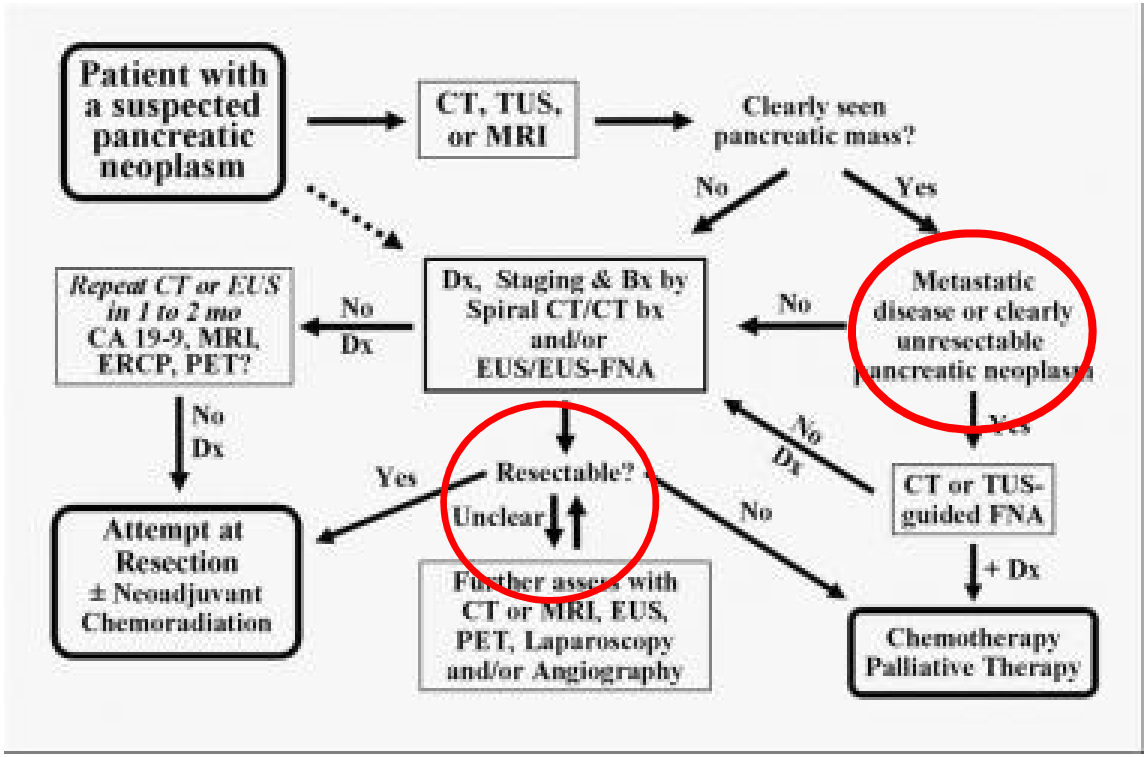

Table 3

TNM Staging of Pancreatic Adenocarcinoma

Primary Tumor (T)

T1	Tumor limited to pancreas, size ≤ 2 cm in greatest dimension
T2	Tumor limited to pancreas, size > 2 cm in greatest dimension
T3	Tumor infiltration (extension) into duodenum, bile duct, papilla, or peripancreatic tissue (retroperitoneal and mesenteric fat, mesocolon, greater/lesser sac, and peritoneum)
T4	Tumor infiltration (extension) into stomach, spleen, colon, or adjacent large vessels (portal vein, superior mesenteric vessels, celiac trunk, hepatic artery, but not splenic vessels)

Regional Lymph Nodes (N)

N0	No regional lymph node metastasis
N1	Regional lymph node metastasis
pN1a	Metastasis in a single regional lymph node
pN1b	Metastasis in multiple regional lymph nodes

Distant Metastases (M)

M0	No distant metastasis
M1	Distant metastasis

Stage Grouping

Stage	T	N	M
I	1	0	0
	2	0	0
II	3	0	0
III	1	1	0
	2	1	0
	3	1	0
IVA	4	Any	0
IVB	Any	Any	1

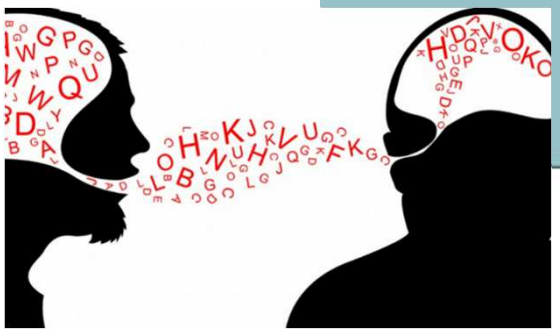
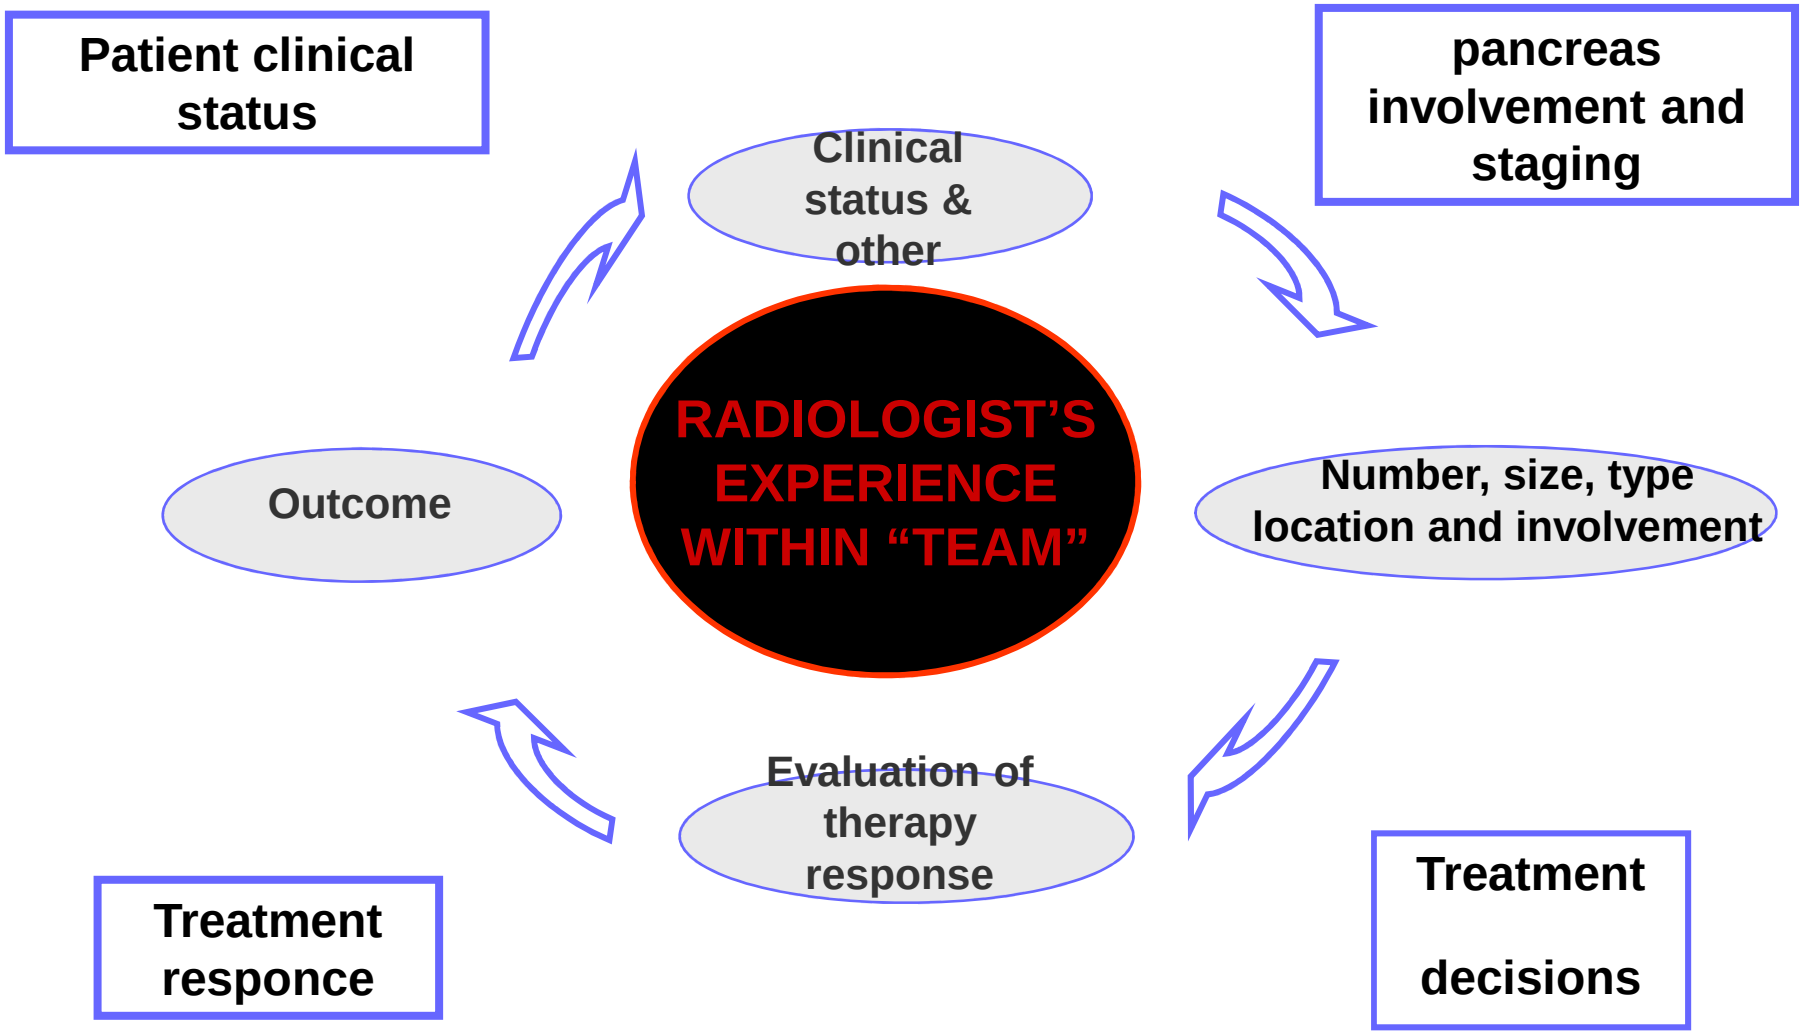
Structured Reporting of Multiphasic CT for Pancreatic Cancer: Potential Effect on Staging and Surgical Planning[1]

Radiology

Conclusion: Structured reporting of pancreatic multiphasic CT provided superior evaluation of pancreatic cancer and facilitated surgical planning. Surgeons were more confident regarding decisions about tumor resectability when they reviewed structured reports before review of multiphasic CT images.



Diagnosi e Management



Take home messages

- Lesioni cistiche: RM
- Lesioni solide
- Diagnosi: ECOGRAFIA
- Caratterizzazione: CEUS/TC
- Casi difficili (maligno vs benigno): RM
- Tipizzazione cito/istologica: ECOENDOSCOPIA
- Stadiazione: TC (RM per eventuali lesioni secondarie epatiche)
- Team multidisciplinare
